Global Mortality 2000: Impact of Blood Pressure and Cholesterol

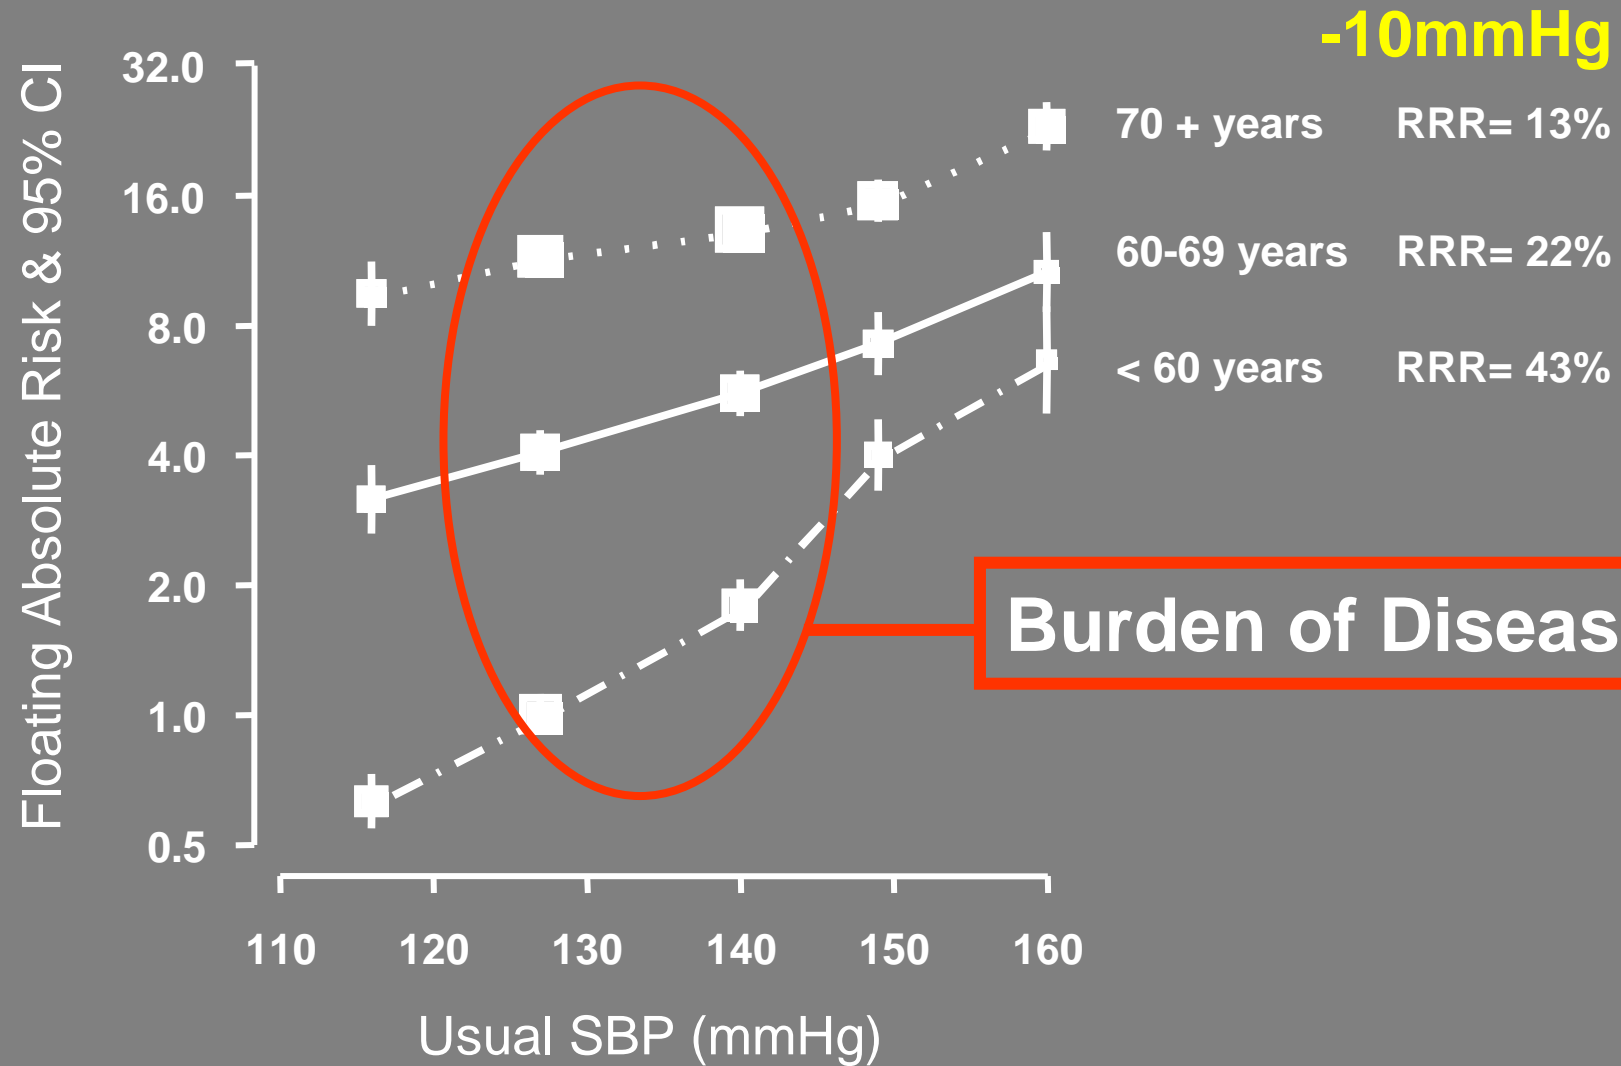

What Is Normal Cholesterol?

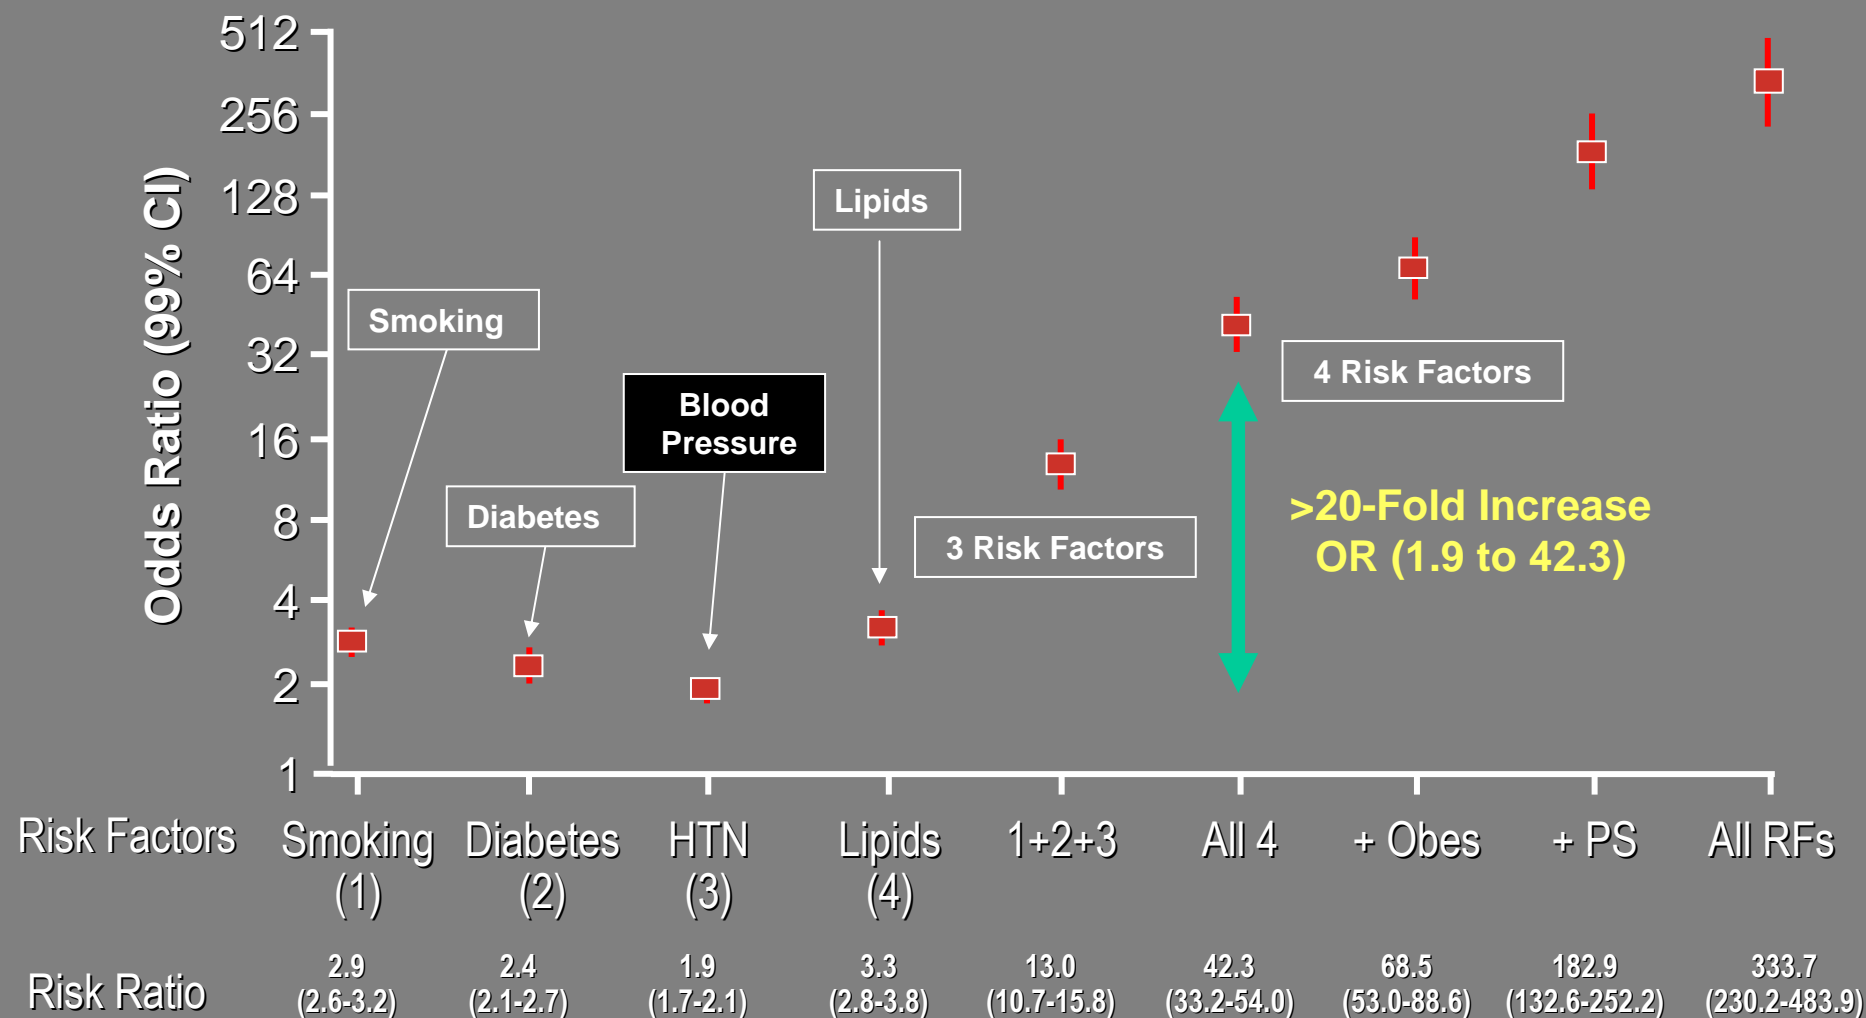

Relative risk of death (\pm SD) from CHD by quartiles of baseline total cholesterol in 9021 Chinese people with 8-13 years' follow-up.

Chen Z, et al. *BMJ*. 1991;303:276-282.

Coronary disease by usual SBP

Increased Number of CV Events (MI) in Patients With Hypertension Plus Other CV Risk Factors

HTN = hypertension; MI = myocardial infarction; PS = psychosocial.

Reproduced with permission from Yusuf S, et al. *Lancet*. 2004;364:937-952.

Rosuvastatin to Prevent Vascular Events in Men and Women with Elevated C-Reactive Protein

Paul M Ridker, M.D., Eleanor Danielson, M.I.A., Francisco A.H. Fonseca, M.D., Jacques Genest, M.D., Antonio M. Gotto, Jr., M.D., John J.P. Kastelein, M.D., Wolfgang Koenig, M.D., Peter Libby, M.D., Alberto J. Lorenzatti, M.D., Jean G. MacFadyen, B.A., Børge G. Nordestgaard, M.D., James Shepherd, M.D., James T. Willerson, M.D., and Robert J. Glynn, Sc.D., for the JUPITER Study Group*

We randomly assigned 17,802 apparently healthy men and women with low-density lipoprotein (LDL) cholesterol levels of less than 130 mg per deciliter (3.4 mmol per liter) and high-sensitivity C-reactive protein levels of 2.0 mg per liter or higher to rosuvastatin, 20 mg daily, or placebo

Table 3. Outcomes According to Study Group.

End Point	Rosuvastatin (N= 8901)		Placebo (N= 8901)		Hazard Ratio (95% CI)	P Value
	No. of Patients	Rate per 100 person-yr	No. of Patients	Rate per 100 person-yr

Abbreviations: HR, hazard ratio; PH, proportional hazards.

^aThe HRs were estimated from Cox PH models adjusting for age and race/ethnicity.

^bThe HRs were estimated from Cox PH models, adjusting for age, race/ethnicity, education, cigarette smoking, BMI, physical activity, alcohol intake, energy intake, family history of DM, hormone therapy use, study arms, and self-report of cardiovascular disease at baseline.

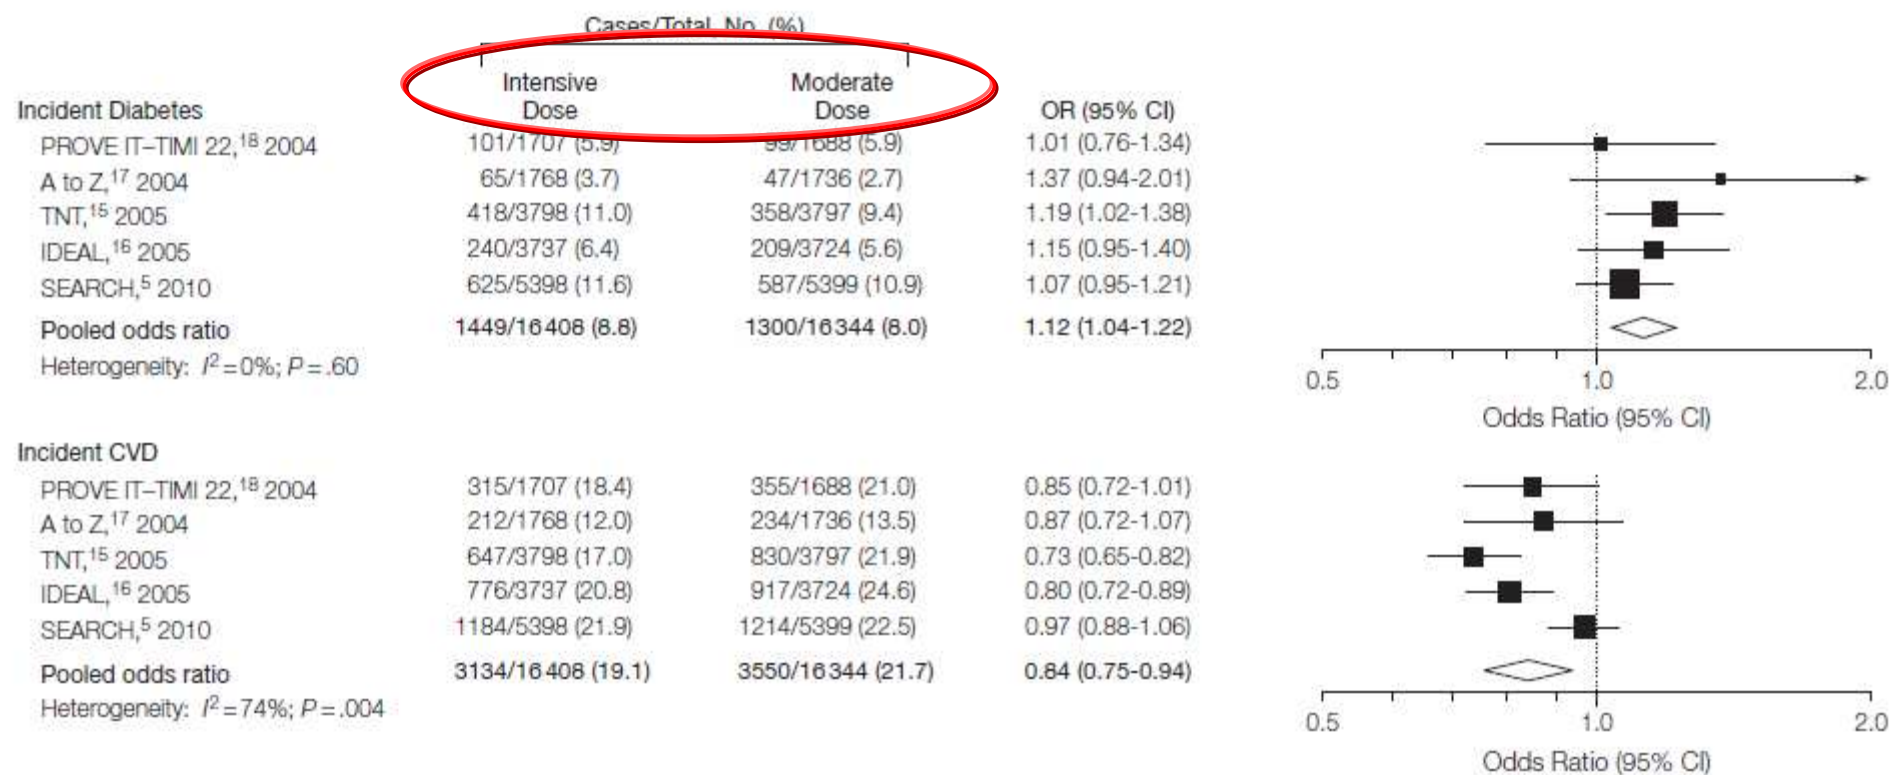

Statins and risk of incident diabetes: a collaborative meta-analysis of randomised statin trials

Risk of Incident Diabetes With Intensive-Dose Compared With Moderate-Dose Statin Therapy

A Meta-analysis

Figure 2. Meta-analysis of New-Onset Diabetes and First Major Cardiovascular Events in 5 Large Trials Comparing Intensive-Dose to Moderate-Dose Statin Therapy

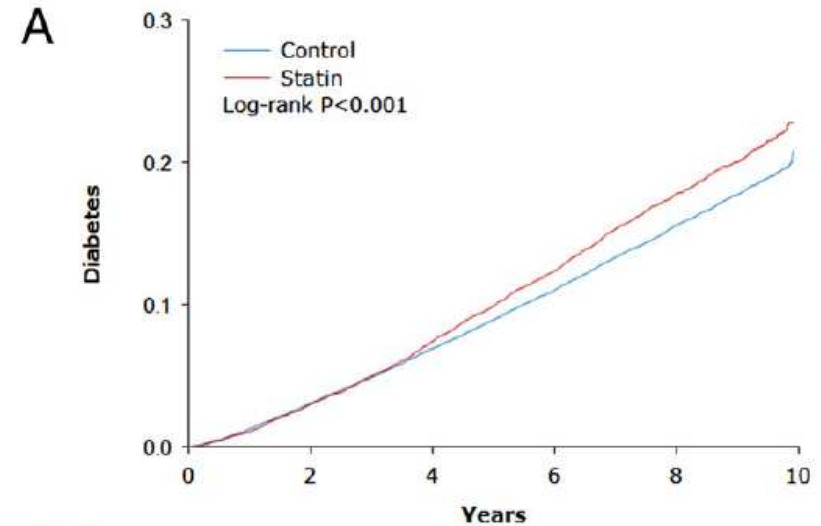

Data marker size indicates relative weight of the studies; OR, odds ratio; and CI, confidence interval.

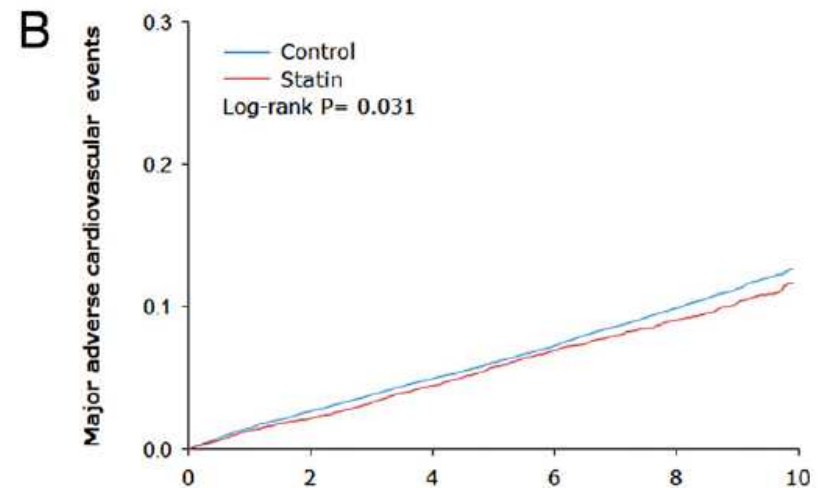

Statins, Risk of Diabetes, and Implications on Outcomes in the General Population

Kang-Ling Wang, MD,*†‡ Chia-Jen Liu, MD,† Tze-Fan Chao, MD,†‡ Chi-Ming Huang, Cheng-Hsueh Wu, MD,†‡ Su-Jung Chen, MD,†‡ Tzeng-Ji Chen, MD, PhD,§|| Shing-Jong Lin, MD, PhD,*†‡¶|| Chern-En Chiang, MD, PhD*†‡¶||
Taipei, Taiwan

During the median follow-up of 7.2 years (interquartile range: 6.1 to 8.7 years), there were 5,754 cases of incident diabetes. Kaplan-Meier curves suggested statin use increased the hazards of diabetes occurrence (HR: 1.15; 95% CI: 1.08 to 1.22; p 0.001).

No. at risk						
Control	33648	30201	26636	22353	9733	77
Statin	8412	7978	7415	6656	3019	24

ESH 2009

The benefit of combining a statin with antihypertensive treatment in hypertensive patients was well established by the **ASCOT-LLA** study, as summarized in the 2007 ESH/ESC guidelines.

The negative results obtained with another statin in the ALLHAT study can be attributed to insufficient lowering of total cholesterol (11% in ALLHAT as compared with 20% in ASCOT).

The beneficial effect of statin administration to patients without previous cardiovascular events has been strengthened by the findings of the **JUPITER study**, showing that lowering LDL-cholesterol by 50% in patients with baseline values less than 130 mg/dl (3.4 mmol/l), but elevated C-reactive protein (CRP), reduced cardiovascular events by 44%.

In conclusion, the recommendation given in the 2007 guidelines to consider **statin therapy in hypertensive patients who have an estimated 10-year risk of cardiovascular events more than 20% can be reconfirmed**, but the JUPITER study suggests that statin benefits can be observed also in patients with elevated CRP and at moderate cardiovascular risk (about 15% cardiovascular events in 10 years).

Rationale, design, and baseline data of the Japanese Primary Prevention Project (JPPP)—A randomized, open-label, controlled trial of aspirin versus no aspirin in patients with multiple risk factors for vascular events

Tamio Teramoto, MD, PhD,^a Kazuyuki Shimada, MD, PhD,^b Shinichiro Uchiyama, MD, PhD,^c Masahiro Sugawara, MD,^d Yoshio Goto, MD, PhD,^d Nobuhiro Yamada, MD, PhD,^c Shinichi Oikawa, MD, PhD,^f Katsuyuki Ando, MD, PhD,^g Naoki Ishizuka, PhD,^h Tsutomu Yamazaki, MD, PhD,ⁱ Kenji Yokoyama, MD, PhD,^j Mitsuru Murata, MD, PhD,^k and Yasuo Ikeda, MD, PhD^l *Tokyo, Tochigi, and Ibaraki, Japan*

Background Prevention of atherosclerotic disease has become an important public health priority in Japan due to the aging of the population and changes in diet and lifestyle factors.

Methods The Japanese Primary Prevention Project (JPPP) is a multicenter, open-label, randomized, parallel-group trial that is evaluating primary prevention with low-dose aspirin in Japanese patients aged 60 to 85 years with hypertension, dyslipidemia, or diabetes mellitus. The study cohort will be followed for a mean of 4 years. The primary end point is a composite of death from cardiovascular causes (including fatal myocardial infarction [MI], fatal stroke, and other cardiovascular death), nonfatal stroke (ischemic or hemorrhagic), and nonfatal MI. Key secondary end points include a composite of cardiovascular death, nonfatal stroke, nonfatal MI, transient ischemic attack, angina pectoris, or arteriosclerotic disease requiring surgery or intervention; each component of the primary end point; noncerebrovascular and noncardiovascular death; and extracranial hemorrhage requiring transfusion or hospitalization. End point assessment is done by a central adjudication committee that is blinded to treatment assignments.

Results Enrollment began in March 2005 and was completed in June 2007. A total of 14,466 patients were randomly allocated to receive enteric-coated aspirin, 100 mg/d, or no aspirin. At randomization, the study cohort had a mean (SD) age of 70.6 (6.2) years; 57.8% were women, 85.0% had hypertension, 71.7% had dyslipidemia, and 33.9% had diabetes. In the study cohort, 80.4% of patients had ≥ 3 risk factors.

ESH 2009

In conclusion, the prudent recommendations of the 2007 ESH/ESC guidelines can be reconfirmed: antiplatelet therapy, in particular low-dose aspirin, should be prescribed to hypertensive patients with previous cardiovascular events;

It can also be considered in hypertensive patients without a history of cardiovascular disease with reduced renal function or with a high cardiovascular risk.

In patients receiving aspirin, careful attention should always be given to the increased possibility of bleeding, particularly gastrointestinal.
